## Introduction

#### **Estimation Problems**

In vision, we are frequently confronted with estimation problems in which parameters of some function must be estimated from measurements.

Some examples of important estimation problems:

- 2D homography: Given a set of points  $x_i$  in  $\mathbb{P}^2$  and corresponding points  $x_i'$  in  $\mathbb{P}^2$ , find a homography taking each  $x_i$  to  $x_i'$ .
- 3D to 2D camera projection: Given a set of points  $X_i$  in 3D space and corresponding points  $x_i$  in an image, find the 3D to 2D projective mapping taking each  $X_i$  to  $x_i$ .
- Fundamental matrix computation: Given a set of points  $x_i$  in one image and a set of corresponding points  $x'_i$  in another image, find the fundamental matrix F relating the two images.
- Trifocal tensor computation: Given a set of point correspondences  $x_i \leftrightarrow x_i' \leftrightarrow x_i''$  across three images, compute the trifocal tensor  $\mathcal{T}_i^{jk}$  relating points or lines in three views.

dsai.asia Computer Vision 4/7

#### Introduction

#### Homography estimation

First we'll consider homography estimation.

We have a set of points  $x_i$  and corresponding points  $x_i'$ . We want to compute H such that  $\forall i, \exists x_i = x_i'$ .

How many points do we need?

- We already saw that each point correspondence gives us 2 constraints (equations), one for the x component and one for the y component.
- Since H has 8 degrees of freedom we need at least 4 correspondences.

dsai.asia Computer Vision 5 / 72

#### Introduction

#### Cost functions

We know that 4 correspondences yields an exact solution.

Due to measurement error and correspondence error we should get more than 4 correspondences then find the homography H minimizing some cost function.

Gold Standard algorithm (Hartley and Zisserman, 2004)

An estimation algorithm minimizing the cost function that is the best possible cost function under certain assumptions.

All algorithms should be evaluated with respect to the Gold Standard.

dsai.asia Computer Vision 7 / 72

Another view of the homography estimation problem

Now we'll look at another way to derive the exact linear estimate of H from 4 points.

For corresponding points  $x_i \leftrightarrow x_i'$  we want  $x_i' = k_i H x_i$  for some nonzero scaling factor k.

Thus we can say that  $x'_i$  and  $Hx_i$  must be collinear.

Recall that the cross product of two collinear vectors is the 0 vector.

This means we can write this constraint in the form  $x_i' \times Hx_i = 0$ .

dsai.asia Computer Vision 8 / 72

Deriving the linear system

Let's use  $h^j$  to denote the j-th row of H written as a vector. Then we have

$$Hx_i = \begin{pmatrix} h^{1T}x_i \\ h^{2T}x_i \\ h^{3T}x_i \end{pmatrix}.$$

Now if  $x'_i = (x'_i, y'_i, w'_i)^T$ , the cross product can be written

$$x'_{i} \times Hx_{i} = \begin{pmatrix} y'_{i}h^{3T}x_{i} - w'_{i}h^{2T}x_{i} \\ w'_{i}h^{1T}x_{i} - x'_{i}h^{3T}x_{i} \\ x'_{i}h^{2T}x_{i} - y'_{i}h^{1T}x_{i} \end{pmatrix}.$$

dsai.asia Computer Vision 9/7

Deriving the linear system

Since we want the cross product to be the zero vector, we can write the linear system

$$\begin{bmatrix} 0^T & -w_i'\mathsf{x}_i^T & y_i'\mathsf{x}_i^T \\ w_i'\mathsf{x}_i^T & 0^T & -x_i'\mathsf{x}_i^T \\ -y_i'\mathsf{x}_i^T & x_i'\mathsf{x}_i^T & 0^T \end{bmatrix} \begin{pmatrix} \mathsf{h}^1 \\ \mathsf{h}^2 \\ \mathsf{h}^3 \end{pmatrix} = 0.$$

We have three linear equations in 9 unknowns. The third equation is actually a linear combination of the first two.<sup>1</sup> So we can drop it (see next slide)...

dsai.asia Computer Vision 10 / 72

<sup>&</sup>lt;sup>1</sup>To convince yourself of this, use the factor  $-x_i'/w_i'$  for the first equation and  $-y_i'/w_i'$  for the second equation.

Deriving the linear system

Dropping the redundant third equation in the parameters of H, we have:

$$A_{i}h = \begin{bmatrix} 0^{T} & -w'_{i}x_{i}^{T} & y'_{i}x_{i}^{T} \\ w'_{i}x_{i}^{T} & 0^{T} & -x'_{i}x_{i}^{T} \end{bmatrix} \begin{pmatrix} h^{1} \\ h^{2} \\ h^{3} \end{pmatrix} = 0.$$
 (1)

However, if  $w_i'=0$  we have an ideal point, and the first two equations become linearly dependent. In this case we should use the third equation and the first or second equation, or just use all three equations all the time.

dsai.asia Computer Vision 11/72

Deriving the linear system

With 8 equations in 9 unknowns, A is  $8 \times 9$  and has rank 8. It has a one-dimensional null space and we obtain  $h = \mathcal{N}(A)$ .

If we have more than 4 correspondences the system Ah = 0 will be over-determined:

- With perfect measurement, the rank of A would still be 8 and it would still have a one-dimensional null space.
- But measurement noise means no exact solution.
- So we try to find the vector h minimizing some cost function.

Since we want Ah to be as close as possible to 0, a sensible cost function is the norm of Ah, i.e.,  $\|Ah\|$ .

However we must avoid the trivial solution h = 0, so we impose a constraint ||h|| = 1. This is OK since H is homogeneous.

dsai.asia Computer Vision 12 / 72

Solving the linear system

So now we have the minimization problem

$$\hat{\mathbf{h}} = \mathop{\text{argmin}}_{\mathbf{h}} \|\mathbf{A}\mathbf{h}\|, \text{subject to } \|\mathbf{h}\| = 1.$$

whose solution is to let h be the unit eigenvector of  $A^TA$  with the smallest eigenvalue, or the unit singular vector of A corresponding to the smallest singular value of A.

This is important to remember: to solve an overconstrained homogeneous linear system Ax = 0 by minimizing  $\|Ah\|$  subject to  $\|h\| = 1$ , we perform SVD on A (see next section) or compute the eigenvector corresponding to the smallest eigenvalue of  $A^TA$ .

dsai.asia Computer Vision 13/72

The basic DLT for H

## **DLT**: Objective

Given  $n \ge 4$  2D to 2D point correspondences  $\{x_i \leftrightarrow x_i'\}$ , determine the 2D homography matrix H such that  $x_i' = Hx_i$ .

## DLT: Algorithm

- (i) For each correspondence  $x_i \leftrightarrow x_i'$ , compute the matrix  $A_i$  as in equation (1). When  $w_i' = 0$ , use different rows.
- (ii) Assemble the  $n \times 2 \times 9$  matrices  $A_i$  into a single  $2n \times 9$  matrix A.
- (iii) Obtain the SVD  $A = UDV^T$ . The unit singular vector (column of V) corresponding to the smallest singular value (diagonal element of D) is the desired A.
- (iv) Rearrange h to obtain H.

4回 > 4월 > 4호 > 4호 > 호 → 9

dsai.asia Computer Vision 14/72

Similar approaches

Other methods: we can select one element of h to be equal to 1 (or any other arbitrary value) to obtain an inhomogeneous linear system which can be solved by the usual least squares methods (see text).

We can also compute H in the same way using line correspondences or conic correspondences. The derivations are quite similar.

dsai.asia Computer Vision 15/72

Example code

For example code for the DLT in Octave, see dlt\_demo.m on the course Web site.

# Singular value decomposition (SVD) Definition

The SVD is an incredibly useful factorization, particularly for the kinds of estimation problems that come up in computer vision.

# Singular Value Decomposition

Given an  $m \times n$  matrix A, the singular value decomposition of A is

$$A = UDV^T$$

where the columns of  $U \in \mathbb{R}^{m \times m}$  and  $V \in \mathbb{R}^{n \times n}$  are orthogonal unit vectors and  $D \in \mathbb{R}^{m \times n}$  is a diagonal matrix whose elements  $\sigma_i$ , with  $\sigma_1 \geq \cdots \geq \sigma_p \geq 0$ ,  $(p = \min(m, n))$ , are called the singular values of A.

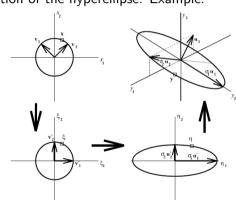

dsai.asia Computer Vision 18 / 72

# Singular value decomposition (SVD)

#### Geometric interpretation

Writing  $A = UDV^T$  models the transformation y = Ax as a rotation, a "stretch" of the unit hypershpere into a hyperellipse, and a rotation of the hyperellipse. Example:

$$\mathbf{A} = \frac{1}{\sqrt{2}} \begin{bmatrix} \sqrt{3} & \sqrt{3} \\ -3 & 3 \\ 1 & 1 \end{bmatrix}$$

Example from Tomasi (2004), Section 3.

dsai.asia Computer Vision 19 / 72

## The SVD has many useful properties:

- If m=n and  $\sigma_i \neq 0, \forall i$ , then A is invertible. The ratio  $C=\sigma_1/\sigma_n$  is called the condition number of A and tells us how close A is to singularity. When 1/C is close to numerical precision, we say A is ill-conditioned and should be considered singular.
- The number of nonzero  $\sigma_i$  is the rank of A. Numerically, we must specify a tolerance, e.g.  $\epsilon = 10^{-6}$ , and say the number of singular values greater than  $\epsilon$  is the rank of A.
- We can get the inverse or pseudoinverse of A using the SVD:  $A^{-1} = VD^{-1}U^T$  or  $A^+ = VD_0^{-1}U^T$ , where  $D_0^{-1}$  is  $D^{-1}$  for the nonzero singular values and 0 otherwise.

20 / 72

dsai.asia

#### Properties of the SVD

## More properties:

- The columns of U corresponding to the nonzero  $\sigma_i$  span the range of A. The columns of V corresponding to the zero singular values span the null space of A.
- The squares of the nonzero singular values of A are the nonzero eigenvalues of  $A^TA$  and  $AA^T$ . The columns of U are the eigenvectors of  $AA^T$  and the columns of V are the eigenvectors of  $A^TA$ . Additionally, we can write  $Au_k = \sigma_k v_k$  and  $A^Tv_k = \sigma_k u_k$  where  $v_k$  is the kth column of V and  $u_k$  is the kth column of U.
- The singular values of A are related to the Frobenius norm of A:

$$\|\mathbf{A}\|_F^2 = \sum_{i,j} a_{i,j}^2 = \sum_i \sigma_i^2.$$

dsai.asia Computer Vision 21/72

# Singular value decomposition (SVD)

**Applications** 

Here are some of the SVD's many uses:

- In inhomogeneous linear least squares problems (Ax = b), we use the SVD to obtain the pseudoinverse of A and let  $x = A^+b$ .
- In homogeneous least squares problems, when we want to minimize  $\|Ax\|$  subject to  $\|x\| = 1$ , we obtain the SVD and let x be the last column of V (since it is also the least eigenvector of  $A^TA$ ).
- In some cases we can use the SVD to enforce constraints on an estimated matrix. For example, if we obtain an estimate R of a rotation matrix that is not quite orthogonal, we can compute the orthogonal matrix  $\hat{R} = \text{UIV}^T$  that is closest to R measured by the Frobenius norm. We can use a similar approach for rank constraints.

#### Algebraic distance

DLT minimizes  $\|Ah\|$ . The vector  $\epsilon = Ah$  is called the <u>residual vector</u>. Each of the components of  $\epsilon$  comes from one of the individual correspondences generating a row of A.

The part of the vector  $\epsilon_i$  contributed by one correspondence  $x_i \leftrightarrow x_i'$  is called the algebraic error for correspondence i and homography H. The norm of  $\epsilon_i$  is called the algebraic distance between  $x_i'$  and  $Hx_i$ .

The algebraic distance is a convenient cost function because it leads to a straightforward linear solution, but it is not geometrically or statistically meaningful!

We will find that normalization is crucial to obtaining good results from algorithms minimizing algebraic error.

We will also look at algorithms that use DLT and similar linear algebraic error-minimizing routines to obtain an initial solution, then minimize a statistical or geometrical cost function from there.

dsai.asia Computer Vision 24 / 72

#### Geometric error

Here we'll use x to represent a measured image point,  $\hat{x}$  to denote an estimated point, and  $\bar{x}$  to represent the true value of a point.

As a starting point, imagine we have perfect measurements in the first image and error in the second image.

Let d(x,y) be the Euclidean distance between the inhomogeneous representations of points x and y.

We call the transfer error for the set of correspondences

$$\sum_{i} d(\mathsf{x}_{i}',\mathsf{H}\bar{\mathsf{x}}_{i})^{2}.$$

We can estimate the homography  $\hat{\mathtt{H}}$  minimizing the transfer error.

dsai.asia Computer Vision 25 / 72

#### Geometric error

In most practical situations, we don't actually know the true position  $\bar{x}_i$  of the point  $x_i$ . Then it makes sense to measure the symmetric transfer error, i.e., the transfer error in both directions:

$$\sum_i d(\mathsf{x}_i, \mathsf{H}^{-1}\mathsf{x}_i')^2 + d(\mathsf{x}_i', \mathsf{H}\mathsf{x}_i)^2.$$

We can estimate the homography  $\hat{H}$  minimizing the symmetric transfer error.

dsai.asia Computer Vision 26 / 72

#### Reprojection error

Another approach is to come up with not only an estimate  $\hat{H}$ , but also estimates  $\hat{x}_i$  and  $\hat{x}_i'$  of the true points  $\bar{x}_i$  and  $\bar{x}_i'$ , ensuring that  $\hat{H}\hat{x}_i = \hat{x}_i'$ .

In this case we want to minimize the reprojection error

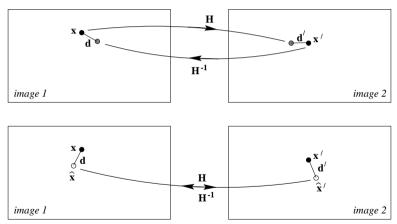

$$\sum_{i} d(\mathbf{x}_{i}, \hat{\mathbf{x}}_{i})^{2} + d(\mathbf{x}'_{i}, \hat{\mathbf{x}}'_{i})^{2}, \text{ subject to } \hat{\mathbf{x}}'_{i} = \hat{\mathbf{H}} \hat{\mathbf{x}}_{i}, \forall i.$$

Reprojection error will be the natural cost function when we are estimating 3D world points  $X_i$  projecting to  $x_i$  and  $x'_i$ .

dsai.asia Computer Vision 27 / 72

## Comparison of transfer error and reprojection error

Here is a comparison of symmetric transfer error and reprojection error:

Hartley and Zisserman (2004), Fig. 4.2

#### Comparison of algebraic and geometric distance

The algebraic and geometric methods turn out to be equivalent whenever  $\hat{w}_i' = w_i' = 1, \forall i$ .

This is always true in the case that H is an affinity, and the DLT specializes to affinities without any problem (just set  $h_7 = h_8 = 0$  in Equation (1)).

dsai.asia Computer Vision 29 / 72

Other cost functions

There are other cost functions that attempt to model the simplicity of algebraic error while approximating geometric error as closely as possible.

One is the Sampson error. See text for details.

dsai.asia Computer Vision 30 / 72

#### Maximum likelihood estimation

If we assume spherical Gaussian measurement errors in one image, the maximum likelihood estimate of H is the one minimizing the transfer error

$$\sum_{i} d(\mathbf{x}_{i}', \mathbf{H}\bar{\mathbf{x}}_{i})^{2}.$$

If we assume spherical Gaussian measurement errors in both images, the maximum likelihood estimate of H turns out to be the one minimizing the reprojection error

$$\sum_i d(\mathsf{x}_i,\hat{\mathsf{x}}_i)^2 + d(\mathsf{x}_i',\hat{\mathsf{x}}_i')^2.$$

See text for the derivations. Notice that maximum likelihood with a Gaussian noise model often leads to least-squares methods.

dsai.asia Computer Vision 31/72

#### Maximum likelihood estimation

That geometric error cost functions arise from maximum likelihood means they have good theoretical justification: they are statistically optimal under certain assumptions.

Is the assumption of Gaussian measurement noise reasonable?

It is reasonable if care is taken to eliminate outliers prior to performing the estimation.

# Normalization

#### Problem with the DLT

What happens with the DLT when we replace  $x_i$  by  $Tx_i$  and replace  $x_i'$  by  $T'x_i'$  for arbitrary homographies T and T'?

- We would prefer the DLT to give us a transformed homography  $\tilde{H} = T'HT^{-1}$ , where H is the homography we would obtain from the DLT using the untransformed points.
- If this were the case, we would get the same estimated homography regardless of the image coordinate system, origin, etc.
- However, it doesn't turn out that way! The DLT is not transformation invariant.

The DLT's lack of transformation invariance is a big problem but can be minimized through data normalization.

Geometric error minimization, on the other hand, is invariant to similarity transformations.

dsai.asia Computer Vision 34 / 72

# Normalization

Fixing the problem with the DLT

Hartley and Zisserman find it is possible to pre-normalize  $x_i$  and  $x'_i$  with isotropic scaling to obtain reasonable solutions:

# Isotropic scaling

- Transform the coordinates in each image so their centroid is at the origin.
- Then scale the coordinates so that the average distance from the origin along each dimension is 1. In 2D, this means the average magnitude of  $(x_i, y_i)^T$  becomes  $\sqrt{2}$ .

With isotropic scaling, the DLT becomes invariant to similarity transformations.

Data normalization is an *essential* step in the DLT algorithm. It must *not* be considered optional (Hartley and Zisserman, 2004, p. 108).

dsai.asia Computer Vision 35 / 72

# Normalization

The normalized DLT for H

# Normalized DLT: Objective

Given  $n \ge 4$  2D to 2D point correspondences  $\{x_i \leftrightarrow x_i'\}$ , determine the 2D homography matrix H such that  $x_i' = Hx_i$ .

# Normalized DLT: Algorithm

- (i) Compute a similarity transform T consisting of a translation and a scale that takes  $x_i$  to  $\tilde{x}_i$  such that the centroid is  $(0,0)^T$  and the average distance from the origin is  $\sqrt{2}$ .
- (ii) Do the same for  $x'_i$ , estimating a similarity T' taking  $x'_i$  to  $\tilde{x}'_i$ .
- (iii) Apply the basic DLT to obtain  $\tilde{H}$  from  $\tilde{x}_i$  and  $\tilde{x}'_i$ .
- (iv) Return  $H = T'^{-1}HT$ .

dsai.asia Computer Vision 36 / 72

# Outline

- Introduction
- 2 Direct Linear Transform (DLT)
- 3 Singuar value decomposition (SVD)
- Cost functions
- Mormalization
- 6 Iterative minimization
- Gold Standard algorithm
- Robust estimation

dsai.asia Computer Vision 37 / 72

#### Motivation

We saw that the DLT is a simple algorithm that minimizes the algebraic error.

However, we would prefer to minimize the geometric error, not the algebraic error.

For some problems, geometric error can be minimized analytically, but more often minimizing geometric error requires iterative methods such as Gauss-Newton.

The advantage of iterative minimization methods are their power. But they have many disadvantages compared to linear minimization techniques like the DLT:

- They are slower.
- They generally need an initial estimate.
- The might not always converge.
- Finding the right stopping criterion can be difficult.

dsai.asia Computer Vision 38 / 72

Formulating the problem

Here are Hartley and Zisserman's steps for implementing an iterative minimization algorithm:

- Decide on a cost function such as reprojection error.
- Find a suitable parameterization of the entity to be estimated. Over-parameterization is usually OK and even beneficial (see text).
- Write a function specification expressing the cost as a function of the parameters.
- Use a linear method such as the DLT for initialization of the parameters.
- Starting from the initial solution, perform iteration to minimize the cost function.

We will consider as an example the problem of minimizing reprojection error for the homography estimation problem.

#### Function specification

A large class of cost functions can be formulated in terms of Mahalanobis distance between a measurement vector  $X \in \mathbb{R}^N$  and points on a model submanifold  $S \subset \mathbb{R}^N$ .

We formulate the problem in terms of a parameter vector  $P \in \mathbb{R}^M$  and write a function  $f : \mathbb{R}^M \mapsto \mathbb{R}^N$  mapping P to an element of the measurement space.

Then the cost function is the squared Mahalanobis distance

$$\|X-f(P)\|_\Sigma^2=(X-f(P))^T\Sigma^{-1}(X-f(P)).$$

- If f(P) is linear, we obtain a solution using a generalized pseudoinverse.
- If f(P) is nonlinear (it usually is in vision problems), we have a nonlinear least squares
  problem that must be solved iteratively. The most common algorithm is
  Levenberg-Marquardt.

Here is the basic iterative scheme:

- $\bullet$  Pick some initial solution  $P_0$  (hopefully close to the actual solution).
- Let k = 0.
- While  $P_k$  is not a minimum of  $||X f(P)||_{\Sigma}^2$ , do:
  - Compute a step  $\delta P$ .
  - Let  $P_{k+1} = P_k + \delta P$ .
  - Let k = k + 1.

To find the best step  $\delta P$ , we try to jump to the new point  $P_k + \delta P$  that would be optimal under some simplified assumptions about f. One technique is to linearize f around  $P_k$ .

dsai.asia Computer Vision 41/72

#### Linearizing f

For vector-valued function  $f(P) = (f_1(P), \dots, f_N(P))^T$ , in the region of P, we can approximate f by the first-order Taylor expansion

$$f(P) = f(P_0 + (P - P_0)) = f(P_0 + \delta P) \approx f(P_0) + J_f(P_0)\delta P,$$

where  $J_f(P_0)$  is the Jacobian of f evaluated at  $P_0$ :

$$\mathbf{J}_{\mathsf{f}}(\mathsf{P}_{\mathsf{0}}) = egin{pmatrix} 
abla f_{\mathsf{1}}^{T}(\mathsf{P}_{\mathsf{0}}) \\ 
\vdots \\ 
abla f_{\mathsf{N}}^{T}(\mathsf{P}_{\mathsf{0}}) \end{pmatrix}$$

and  $\nabla f_i(P_0)$  is the gradient of  $f_i$  evaluated at  $P_0$ , i.e.,

$$\nabla f_i(\mathsf{P}_0) = \left(\frac{\partial f_i}{\partial \mathsf{P}_1}(\mathsf{P}_0), \dots, \frac{\partial f_i}{\partial \mathsf{P}_M}(\mathsf{P}_0)\right)^T.$$

(ロト 4回 ト 4 重 ト 4 重 ) りへ(で)

dsai.asia Computer Vision 42 / 72

Minimizing the linearized f

We've approximated f(P) by the linear function  $f(P_0) + J_f(P_0)(P - P_0)$ .

Let's assume for the moment that we use the  $L_2$  norm ( $\Sigma = I$ ) and that X = 0. Then minimizing  $\|X - f(P)\|_{\Sigma}^2$  just means minimizing

$$E(\mathsf{P}) = \sum_{i=1}^{N} f_i^2(\mathsf{P}).$$

If P is a minimum of E(P), we know that

$$\mathsf{F}(\mathsf{P}) = \frac{1}{2} \nabla \mathsf{E}(\mathsf{P}) = 0.$$

Substituting the definition for E(P) and writing as a matrix equation, we can obtain

$$F(P) = J_f^T(P)f(P) = 0.$$

Now we'll use Newton's method to find the zero of F.

(ロ ▶ ∢御 ▶ ∢き ▶ ∢き ▶ き めのの

#### Minimizing the linearized f

Newton's method for a vector valued fuction F is to solve

$$J_{\mathsf{F}}(\mathsf{P}_k)\delta\mathsf{P} = -\mathsf{F}(\mathsf{P}_k)$$

for  $\delta P$  then jump to  $P_{k+1} = P_k + \delta P$ .

In our case it turns out that

$$J_{\mathsf{F}}(\mathsf{P}) = J_{\mathsf{f}}^{\mathsf{T}}(\mathsf{P})J_{\mathsf{f}}(\mathsf{P}) + \sum_{i=1}^{\mathsf{N}} f_i(\mathsf{P})H_{f_i}(\mathsf{P}).$$

where  $H_{f_i}(P)$  is the Hessian (matrix of second derivatives of  $f_i$ ) evaluated at P.

dsai.asia Computer Vision 44 / 7

Finally, to apply Newton's method we solve the linear system

$$\left[\mathsf{J}_\mathsf{f}^\mathsf{T}(\mathsf{P})\mathsf{J}_\mathsf{f}(\mathsf{P}) + \sum_{i=1}^N f_i(\mathsf{P})\mathsf{H}_{f_i}(\mathsf{P})\right]\delta\mathsf{P} = -\mathsf{J}_\mathsf{f}^\mathsf{T}(\mathsf{P})\mathsf{f}(\mathsf{P}).$$

Crazy! Let's do an example in one dimension to get the idea.

dsai.asia Computer Vision 45/72

Minimizing the linearized f (example)

#### Example in one dimension.

Let  $f(p) = p^2 - 4p + 5$ . We know the minimum is at p = 2.

The "Jacobian" in one dimension is actually just the derivative:

$$J_f(p) = [f'(p)] = [2p-4].$$

The error function is

$$E(p)=f^2(p),$$

so the function we want to find the zero of using Newton's method is

$$F(p) = \frac{1}{2}\nabla E(p) = J_f^T(p)f(p) = (2p-4)(p^2-4p+5).$$

◆ロ > ← 部 > ← 差 > ← 差 → り へ ()

dsai.asia Computer Vision 46 / 72

Minimizing the linearized f (example)

#### Example in one dimension, continued.

To find the zero of F(p), we need

$$J_F(p) = J_f^T(p)J_f(p) + \sum_{i=0}^N f_i(p)H_{f_i}(p)$$
$$= (2p-4)^2 + (p^2 - 4p + 5) \cdot 2$$
$$= 6p^2 - 24p + 26.$$

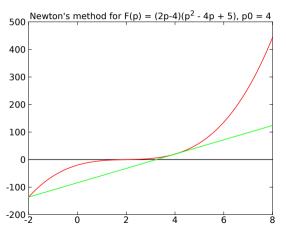

then we solve the linear system

$$J_F(p)\delta p = -F(p).$$

dsai.asia Computer Vision 47/72

Minimizing the linearized f

Suppose our initial guess for the parameter is p = 4.

Minimizing the linearized f

Problem with Newton's method: the Hessians

$$\begin{bmatrix} \frac{\partial^2 f_i}{\partial p_1^2} & \frac{\partial^2 f_i}{\partial p_1 \partial p_2} & \cdots \\ \vdots & \vdots & \vdots \\ \frac{\partial^2 f_i}{\partial p_M \partial p_1} & \frac{\partial^2 f_i}{\partial p_M \partial p_2} & \cdots \end{bmatrix}$$

are tedious and expensive to calculate, especially if M, the dimensionality of the parameter vector, is large.

dsai.asia Computer Vision 49 / 72

dsai asia

Minimizing the linearized f

Because of the difficulty of calculating Hessians we typically use quick-and-dirty approximations rather than explicitly calculate them.

The Gauss-Newton algorithm drops the second-order terms entirely.

The Levenberg-Marquardt algorithm approximates the second order terms by a scaled identity matrix:

$$\left[J_f^T(P)J_f(P) + \mu I\right] \delta P = -J_f^T(P)f(P).$$

where the parameter  $\mu$  is adapted during optimization.

Lucky for us, Levenberg-Marquardt is implemented in many packages: Matlab lsqnonlin(), Octave leasqr(), and *Numerical Recipes in C* mrqmin().

Computer Vision

See the text, Appendix 6, for information on adapting Levenberg-Marquardt to very large problems.

Iterative minimization applied to homography estimation

In the case of homography estimation, we have a set of 2D coordinates of corresponding points  $x_i$  and  $x_i'$ , so the dimensionality of the measurement space is N = 4n and the measurement is a vector  $X \in \mathbb{R}^N$ .

Suppose our parameterization was to choose a set of points  $\hat{x}_i$  in the first image, then choose a homography H.

- The corresponding points  $\hat{x}_i' = \hat{H}\hat{x}_i$  would then be fixed.
- The parameter vector  $P \in \mathbb{R}^M$ , then, would contain the 2n parameters of  $\hat{x}_i$  and the 9 parameters of  $\hat{H}$ , so M = 2n + 9.
- The resulting model (the set of measurements in  $\mathbb{R}^N$  that can be be generated with our parameterization) is a 2n+8 dimensional submanifold  $S \subset \mathbb{R}^N$ .

[Analogy: think about a circle as a 1D submanifold of  $\mathbb{R}^2$ .]

dsai.asia Computer Vision 51/72

Iterative minimization applied to homography estimation

Given the model in the previous page, it is straightforward to write the mapping

$$f:(h,\hat{x}_1,\ldots,\hat{x}_n)\mapsto(\hat{x}_1,\hat{x}'_1,\ldots,\hat{x}_n,\hat{x}'_n)$$

where  $\hat{x}'_i = H\hat{x}_i$ .

The reprojection error cost function becomes  $\|X - f(P)\|^2$ , which is just the Mahalanobis cost function with  $\Sigma = I$ .

This means Levenberg-Marquardt applies. The resulting algorithm is Hartley and Zisserman's Gold Standard MLE algorithm for estimating H.

# Outline

- Introduction
- 2 Direct Linear Transform (DLT)
- 3 Singuar value decomposition (SVD)
- Cost functions
- Mormalization
- 6 Iterative minimization
- Gold Standard algorithm
- Robust estimation

dsai.asia Computer Vision 53 / 72

The Gold Standard algorithm for H tries to find

$$(\hat{\mathbf{H}}, \hat{\mathbf{x}}_1, \dots, \hat{\mathbf{x}}_n) = \underset{\hat{\mathbf{H}}, \hat{\mathbf{x}}_1, \dots, \hat{\mathbf{x}}_n}{\operatorname{argmax}} P(\mathbf{x}_1, \mathbf{x}'_1, \dots, \mathbf{x}_n, \mathbf{x}'_n \mid \mathbf{H}, \hat{\mathbf{x}}_1, \dots, \hat{\mathbf{x}}_n)$$

We know that maximizing the likelihood in the equation, assuming Gaussian measurement error, means minimizing the reprojection error

$$\sum_{i} d(\mathsf{x}_{i}, \hat{\mathsf{x}}_{i})^{2} + d(\mathsf{x}_{i}', \hat{\mathsf{H}} \hat{\mathsf{x}}_{i})^{2}$$

This is a nonlinear least squares problem, which Levenberg-Marquardt can solve, but we need an initial solution, which we can obtain using the DLT.

# Gold Standard algorithm

The algorithm

#### Gold Standard for H: Objective

Given n > 4 image point correspondences  $\{x_i \leftrightarrow x_i'\}$ , determine the maximum likelihood estimate  $\hat{H}$ .

#### Gold Standard

- (i) Compute an initial estimate of  $\hat{H}$  using the normalized DLT.
- (ii) Compute an initial estimate of the subsidiary variables  $\{\hat{x}_i\}$  using  $\{x_i\}$  (see text for a better way).
- (iii) Minimize the cost

$$\sum_{i} d(\mathsf{x}_{i}, \hat{\mathsf{x}}_{i})^{2} + d(\mathsf{x}_{i}', \hat{\mathsf{H}} \hat{\mathsf{x}}_{i})^{2}$$

over  $\hat{H}, \hat{x}_1, \dots, \hat{x}_n$ , using Levenberg-Marquardt over 2n + 9 variables: 2n for the points  $\{\hat{x}_i\}$  and 9 for the homography matrix  $\hat{H}$ .

dsai.asia Computer Vision 55 / 72

# Gold Standard algorithm

Example code

For example code for the Gold Standard algorithm in Octave, see gs\_demo.m on the course Web site.

Note that if you're using Matlab you can use the Matlab port of the Octave leasqr() function or use the Matlab Optimization Toolbox function lsqnonlin(). But be careful as the two functions work a bit differently.

- 3 Singuar value decomposition (SVD)
- Cost functions
- Mormalization
- 6 Iterative minimization
- Gold Standard algorithm
- Robust estimation

dsai.asia Computer Vision 57 / 72

#### Introduction

The Gold Standard algorithm is optimal if the measurement error for the corresponding points  $x_i \leftrightarrow x_i'$  is actually Gaussian.

In practice, though, the points and their correspondences are obtained through an automatic procedure which makes mistakes.

These mistakes, or outliers, will severely disrupt our estimates, so they should be removed.

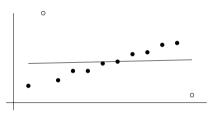

We seek to obtain a set of inliers that will be used for estimation and a set of outliers that will be ignored.

This task is called <u>robust estimation</u> because we want the estimation method to be <u>robust</u> to <u>outliers</u> following an unmodeled error distribution.

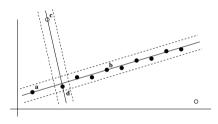

dsai.asia Computer Vision 58 / 72

#### RANSAC motivation

Example: fitting a line x' = ax + b to a set of points.

Least squares fit is skewed by outliers.

RANSAC support for two candidate lines.

The RANSAC (Random Sample Consensus, Fischler and Bolles, 1981) algorithm is one of the many robust methods to solve this problem.

dsai.asia Computer Vision 59 / 72

# Robust estimation RANSAC idea

The idea of RANSAC is that we only need two points to determine a line.

So to begin, we pick two points at random to define a line.

The support for this line is the number of points that lie within a distance threshold t of that line.

We repeat for a while, and the line with the most support is deemed best.

The points within the threshold are called inliers and they are said to make up the consensus set.

In the figure, we see that the line  $\overline{ab}$  has a support of  $\overline{10}$  but the line  $\overline{de}$  has a support of only 2. We would select  $\overline{ab}$  as a better fit to the data than  $\overline{de}$ .

dsai.asia Computer Vision 60 / 72

RANSAC algorithm

Hartley and Zisserman's (2004) adaptation of Fischler and Bolles' (1981) RANSAC:

# RANSAC: Objective

Robust fit of a model to a data set S which contains outliers

## RANSAC: Algorithm

- (i) Randomly select a sample s from S and instantiate the model from s.
- (ii) Find the consensus set (inliers)  $S_i$  within distance threshold t of the model.
- (iii) If  $|S_i| \geq T$  re-estimate the model using all of the points in  $S_i$  and terminate; otherwise repeat from (i).
- (iv) After N trials, select the largest consensus set  $S_i$  and re-estimate the model using all of the points in  $S_i$ .

dsai.asia Computer Vision 61/72

#### RANSAC parameters

#### RANSAC has three free parameters:

- t: the distance threshold,
- T: the minimum number of inliers for early termination,
- N: the number of samples.

t can be determined empirically, or, if the error distribution is known to be Gaussian with standard deviation  $\sigma$ , a 95% or similar confidence interval can be calculated.

See Table 4.2 in the text for reasonable values of t for various vision problems.

dsai.asia Computer Vision 62 / 72

#### RANSAC parameters

N can be determined empirically, or if the proportion w of inliers is approximately known, we can choose N giving (e.g.) a 99% probability that on some iteration we will choose a sample containing inliers only.

Example: in homography estimation our sample size would be 4. If we assume a 50% outlier rate, we should select N = 72 samples to assure a 99% probability of sampling at least one set with 4 inliers.

See Table 4.3 in the text for some example values and how to calculate N in general.

T, the acceptable consensus set size, should be approximately the number of inliers thought to be in the data.

For example, in the case of homography estimation, if we have 100 correspondences and a 50% outlier rate, we should let T=50.

dsai.asia Computer Vision 63 / 72

#### Adaptive version of RANSAC for unknown w

One variant, when the percentage of inliers w is unknown, is adpative RANSAC:

- Initialize  $N=\infty$ .
- While running RANSAC, decrease N whenever you obtain a sample with a bigger consensus set than previously seen.
- Terminate after N iterations.

A bigger consensus set means w is bigger than previously thought, so N need not be so large.

dsai.asia Computer Vision 64/72

#### Robust maximum likelihood estimation

Note that step (iv) of RANSAC was to re-estimate the model from all of the points in  $S_i$ . We should use maximum likelihood in this case.

Problem: the set of inliers could change after we compute the new maximum likelihood model.

We could just accept the estimate anyway.

Some approaches recompute the inliers after obtaining the maximum likelihood model then repeat maximum likelihood model estimation until the consensus set converges.

See text for detailed discussion and other alternative approaches.

dsai.asia Computer Vision 65 / 72

Using RANSAC to estimate H

# Automatic H estimation: Objective

Given two images, compute the homography.

# Automatic H estimation: Algorithm

- (i) Compute a set of interest points in each image.
- (ii) Compute putative correspondences between the point sets.
- (iii) RANSAC robust estimation: Repeat for N samples, where N is determined adaptively as previously described:
  - (a) Select a random sample of 4 correspondences and compute H.
  - (b) Calculate the distance  $d_{\perp}$  for each putative correspondence.
  - (c) Find the number of inliers for which  $d_{\perp} < t = \sqrt{5.99}\sigma$  pixels.
- (iv) Re-estimate H using the inliers and the Gold Standard algorithm
- (v) (Optional) use the new H to recompute the matching set of interest points and repeat from (iv) until convergence.

66 / 72

#### Using RANSAC to estimate H

There are two implementation details that need consideration: how to measure the distance and how to select the samples.

- For distance, the symmetric transfer error  $d_{\text{transfer}}^2 = d(x, H^{-1}x')^2 + d(x', Hx)^2$  is appropriate since it is easy to compute. Reprojection error is better but expensive.
- Widespread distribution of the samples is good, to ensure good interpolation in the rest of the image. The sampler can be biased to pick points in different regions of the image rather than uniformly.

Example results

# Example initial images (Hartley and Zisserman, 2004, Fig. 4.9):

Image 1

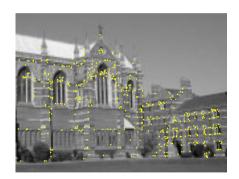

Image 2, related by rotation around camera center

Example results

Detected corners, about 500 on each image.

#### Example results

Initial set of 268 correspondences obtained by SSD of image patches around the corners:

268 putative correspondences, Hartley and Zisserman (2004), Fig. 4.9(e)

117/268 outliers, Hartley and Zisserman (2004), Fig. 4.9(f)

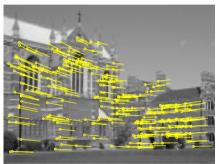

dsai.asia Computer Vision 70 / 72

#### Example results

Final set of 262 correspondences after RANSAC, guided matching, and MLE.

151 inliers consistent with H found by RANSAC, Hartley and Zisserman (2004), Fig. 4.9(g).

Final set of 262 correspondences after guided matching and MLE beginning from the RANSAC solution, Hartley and Zisserman (2004), Fig. 4.9(h).

Implementation

See the course Web site for a test using OpenCV, its built-in Shi-Tomasi feature detector and its built-in RANSAC H estimation function.

See the Torr toolbox at

http://cms.brookes.ac.uk/staff/PhilipTorr/Code/master\_code.htm for a Matlab implementation using the Harris corner detector.

When there is significant rotation and/or scale in the image plane, the SIFT (Scale Invariant Feature Transform) feature detector is much better than Harris or Shi-Tomasi.

There is a large literature on feature detectors enabling correspondence estimation over multiple views.

Transform invariance matching will be very important when we move to multiple views of a general scene and estimate the fundamental matrix F rather than a homography H.
